An electromyogram, or EMG, is a graphical recording of electrical activity within muscles. Activation of muscles by nerves results in changes in ion flow across cell membranes, which generates electrical activity. This can be measured using surface electrodes placed on the skin over the muscle of interest. Electrical activity correlates with strength of muscle contraction, and is dependent on the quantity of nerve impulses which are sent to the muscle.

clinical study of the electrical activity of muscle fibers individually and collectively. This electrical activity can be recorded via surface or needle electrodes, the latter being used far more commonly in the clinical setting, and is evaluated during needle insertion, during periods of rest (spontaneous activity), and during periods of voluntary muscle contraction [ 1 ].
