Three types of uncertainty are included in both uncertainty quantification and model validation: (1) natural variability in loading and material properties; (2) data uncertainty due to measurement errors, sparse data, and different inspection results (crack not detected, crack detected but size not measured, and crack detected with size measurement); and (3) modeling uncertainty and errors during crack growth analysis, numerical approximations, and finite element discretization.

Verification is performed to determine if the computational model fits the mathematical description. Validation is implemented to determine if the model accurately represents the real world application. Uncertainty quantification is conducted to determine how variations in the numerical and physical parameters affect simulation outcomes.

Uncertainty quantification (UQ) is the science of quantitative characterization and reduction of uncertainties in both computational and real world applications. It tries to determine how likely certain outcomes are if some aspects of the system are not exactly known. An example would be to predict the acceleration of a human body in a head-on crash with another car: even if we exactly knew the speed, small differences in the manufacturing of individual cars, how tightly every bolt has been tigh

As computational science and engineering have matured, the process of quantifying or bounding uncertainties in a computational estimate of a physical quality of interest has evolved into a small set of interdependent tasks: verification, validation, and uncertainty of quantification (VUUQ).

Assessing the Reliability of Complex Models: Mathematical ...

From a mathematical perspective, validation is the process of assessing whether or not the quantity of interest (QOI) for a physical system is within some tolerance—determined by the intended use of the model—of the model prediction.

UQ may be defined as the process of quantifying uncertainties associated with model calculations of true, physical quantities of interest (QOIs), with the goals of accounting for all relevant sources of uncertainty and quantifying the contributions of specific sources to the overall uncertainty (National Research Council, 2012).

3. Model Errors - This uncertainty is addressed by validation against relevant experimental data sets. Note that experimental data relevancy arguments need to address scaling issues. 4. Parameter Errors - This is addressed by uncertainty quantification. The hardest part is building the parameter distribution functions. 5.
