To date, numerous stem cells and biomaterials have been explored for a variety of tissue and organ regeneration. The challenge for existing stem cell-based techniques is that current therapies lack controlled environments that are crucial for regulating stem cell engraftment and differentiation in vivo , because stem cells are rather sensitive to even minute changes in their environment.

Tissue and Organ Regeneration: Advances in Micro- and ...

Regenerative medicine is a broad field that includes tissue engineering but also incorporates research on self-healing – where the body uses its own systems, sometimes with help foreign biological material to recreate cells and rebuild tissues and organs. The terms "tissue engineering" and "regenerative medicine" have become largely interchangeable, as the field hopes to focus on cures instead of treatments for complex, often chronic, diseases.

Tissue Engineering and Regenerative Medicine

The primary aim of tissue engineering is to develop fully functional and sustainable tissues and organs in vitro and in vivo for repairing or replacing damaged tissues in the body.1, 2, 3, 4 Approaches involved in tissue engineering have varied among their specific applications such as regeneration of bone, skin, heart, and others. 5 Although there have been many studies performed in that regard, only a few of them have presented successful results from the in vitro level to clinical ...

Regeneration in humans is the regrowth of lost tissues or organs in response to injury. This is in contrast to wound healing, or partial regeneration, which involves closing up the injury site with some gradation of scar tissue. Some tissues such as skin, the vas deferens, and large organs including the liver can regrow quite readily, while others have been thought to have little or no capacity for regeneration following an injury. Numerous tissues and organs have been induced to regenerate. Bla
